## PROGRAMMING IN HASKELL

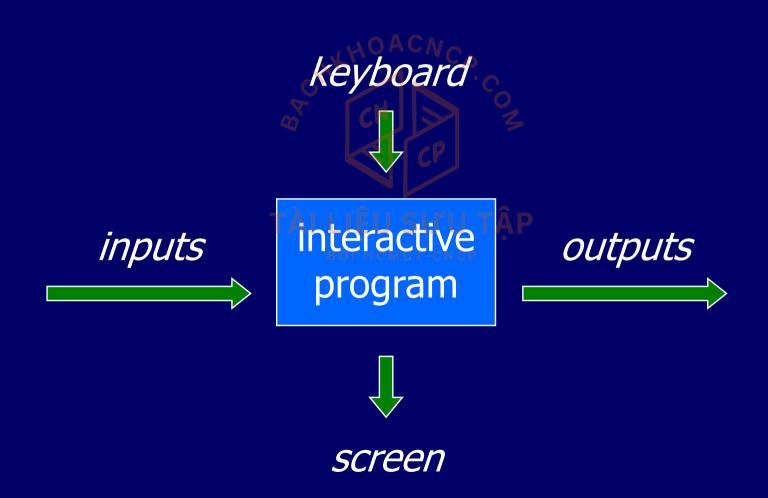

Chapter 10 - Interactive Programming

### Introduction

To date, we have seen how Haskell can be used to write <u>batch</u> programs that take all their inputs at the start and give all their outputs at the end.

However, we would also like to use Haskell to write interactive programs that read from the keyboard and write to the screen, as they are running.

## **The Problem**

Haskell programs are pure mathematical functions:

Haskell programs have no side effects.

However, reading from the keyboard and writing to the screen are side effects:

Interactive programs <u>have side effects</u>.

### **The Solution**

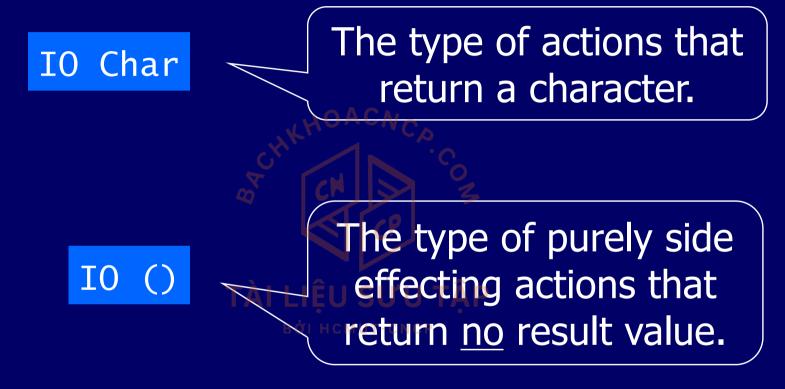

Interactive programs can be written in Haskell by using types to distinguish pure expressions from impure <u>actions</u> that may involve side effects.

IO a

TÀI LIỆU SƯU TẬP

The type of actions that return a value of type a.

#### For example:

#### Note:

() is the type of tuples with no components.

## **Basic Actions**

The standard library provides a number of actions, including the following three primitives:

■ The action <u>getChar</u> reads a character from the keyboard, echoes it to the screen, and returns the character as its result value:

getChar :: IO Char

■ The action <u>putChar c</u> writes the character c to the screen, and returns no result value:

The action return v simply returns the value v, without performing any interaction:

return ::  $a \rightarrow I0 a$ 

# Sequencing

A sequence of actions can be combined as a single composite action using the keyword <u>do</u>.

For example:

## **Derived Primitives**

Reading a string from the keyboard:

Writing a string to the screen:

```
putStr :: String → IO ()
putStr [] = return ()
putStr (x:xs) = do putChar x
putStr xs
```

Writing a string and moving to a new line:

```
putStrLn :: String → IO ()
putStrLn xs = do putStr xs
    putChar '\n'
```

## **Example**

We can now define an action that prompts for a string to be entered and displays its length:

#### For example:

Note:

```
> strlen

Enter a string: Haskell
The string has 7 characters

TAILIEU SUU TAP
```

■ Evaluating an action <u>executes</u> its side effects, with the final result value being discarded.

# Hangman

Consider the following version of hangman:

- One player secretly types in a word.
- The other player tries to deduce the word, by entering a sequence of guesses.
- For each guess, the computer indicates which letters in the secret word occur in the guess.

■ The game ends when the guess is correct.

We adopt a <u>top down</u> approach to implementing hangman in Haskell, starting as follows:

The action <u>sgetLine</u> reads a line of text from the keyboard, echoing each character as a dash:

```
sgetLine :: IO String
sgetLine = do x ← getCh
              if x ==  ' \ n' then
                 do putChar x
              HEU SUTreturn []
              else
                 do putChar '-'
                     xs ← sgetLine
                     return (x:xs)
```

The action <u>getCh</u> reads a single character from the keyboard, without echoing it to the screen:

The function <u>play</u> is the main loop, which requests and processes guesses until the game ends.

```
play :: String \rightarrow IO ()
play word =
   do putStr "?"
      guess ← getLine
      if guess = Word then
         putStrLn "You got it!"
      else
         do putStrLn (match word guess)
             play word
```

The function <u>match</u> indicates which characters in one string occur in a second string:

```
match :: String \rightarrow String \rightarrow String match xs ys = [if elem x ys then x else '-' | x \leftarrow xs]
```

#### TÀI LIỆU SƯU TẬP

For example:

```
> match "haskell" "pascal"
"-as--11"
```

## **Exercise**

Implement the game of <u>nim</u> in Haskell, where the rules of the game are as follows:

■ The board comprises five rows of stars:

#### TÀI LIÊU SƯU TẬP

Two players take it turn about to remove one or more stars from the end of a single row.

■ The winner is the player who removes the last star or stars from the board.

Hint:

TÀI LIỆU SƯU TẬP

Represent the board as a list of five integers that give the number of stars remaining on each row. For example, the initial board is [5,4,3,2,1].
